

Deterioration of the tap water values:

Unfortunately, our tap water values deteriorate more and more. There is more and more chlorination and many pollutants coming into our drinking water.

Therefore, we suggest to use a carbon block filter and rinse the water into the aquarium by using a shower head.

The most easiest way to remove CHLORID from the tap water is by running the water into the aquarium or a bucket, through a shower head with a distance of 10 – 20 centimeters. So, before it gets into your aquarium, chlorine leaves your water. This is very important, because chlorid is very harmful for your fish, or even fatal, depending on the dose.

While running through the shower head, the water jet splits and each water drop comes into contact with air, whereby the chlorine flows out of the water. As a precaution we advise you to always choose this way.

CARBON BLOCK FILTER:

By using a carbon block filter when changing the water, lots of pollutants can be filtered from the water: e. g. chlorid, heavy metals like lead, copper, etc., flavourings, dyes, odoriferous substances, pesticides, medication residues.

Your pet dealer will be happy to advise you.
